1. Supervised learning is a machine learning method where the model learns from labelled data. The correct output is already given with the input data.

2. A variable in python is a name used to store a value, for example, age = 20 stores the value 20 in the variable age

3. A list is mutable so its elements can be changed after creation. A ~~tab~~ tuple is immutable So its elements can not be changed.

4. A list and a tuple are both used to store multiple values in Python. The main difference is that a list is mutable, while a tuple is immutable.

A list is created using square brackets.

eg:- N = [1, 2, 3]

@

A tuple is created using Parantheses, Its elements cannot be changed after it is created.

eg:- n = (1, 2, 3)

Therefore, lists are used when the data May need to be changed, while tuples are useful when the data should remain fixed.
